CAS INDEXING IS AVAILABLE FOR THIS PATENT.

AB Modified enzymes which comprise a catalytically active amino acid sequence of an enzyme, linked via a non-mino acid linking region to an amino acid sequence comprising a Cellulose Binding Domain. The present invention further relates to laundry detergent and/or fabric care compositions comprising such modified enzymes. These compositions provide a higher effective concentration of the enzyme at its substrate location and therefore, improved enzymatic benefits.

AB The present invention relates to a modified enzyme which comprises a

catalytically active amino acid sequence of a transferase linked to an amino acid sequence comprising a Cellulose Binding Domain (CBD). A specific embodiment comprises CBD-transferase, which is dextransucrase or transglutaminase or Toruzyme linked by PEG(NPC)2 to the cellulose-binding domain **Cellulozome** from Clostridium **cellulovorans**. The laundry detergent and/or fabric care compn. preferably further comprises a detergent ingredient selected from an anionic surfactant (alkyl sulfate, alkyl ethoxy sulfate, linear alkylene sulfonate), nonionic surfactant (alkyl ethoxylate), cationic surfactants, enzymes (protease, **cellulase**, lipase, amylase), bleaching agents, dye transfer inhibiting agents, dispersants, and smectite clay. The present invention further relates to laundry detergent and/or fabric care compns. comprising such modified enzyme, for improved fabric care and cleaning benefits.

AB The present invention relates to a modified enzyme and laundry detergent and/or fabric care compns. comprising this modified enzyme. This modified enzyme comprises a catalytically active amino acid sequence of a cellulolytic enzyme **endoglucanase** I linked to an amino acid sequence comprising a Cellulose Binding Domain (CBD). A specific embodiment comprises CBD-Endolase, which is the cellulolytic enzyme core derived from the enzyme sold under the tradename Endolase linked by PEG(NPC)2 (mol. wt. 3400) to the CBD **Cellulozome** from Clostridium **cellulovorans**. The laundry detergent and/or fabric care compns. preferably further comprise a detergent ingredient selected from cationic surfactants, proteolytic enzymes, bleaching agents, builders

(in particular zeolite A and sodium tripolyphosphate) and/or clays. These compns. provide excellent overall cleaning including stain removal and whitening maintenance, while preventing any neg. effect on the fabric. These compns. further provide fabric care, including anti-bobbling, depilling, color appearance, fabric softness and fabric anti-wear properties and benefits, while preventing any neg. effect on the fabric.

AB The present invention relates to a modified enzyme which comprises a catalytically active amino acid sequence of an enzyme, linked via a non-amino acid linking region to an amino acid sequence comprising a Cellulose Binding Domain (CBD). In one embodiment the modified enzyme comprises coupling CBD from Clostridium **cellulovorans** with Endolase (a cellulolytic enzyme from Hansenula insolens) with the PEG linker PEG(NPC)2. CBD conjugates are also prepd. with Savinase (proteolytic enzyme), Purafact (amylolytic enzyme), Lipolase (lipolytic enzyme), Pulpzyme (xylanase), dextransucrase and transferases EC 2.3.2.13 and EC 2.4.1.19, Pectinex (pectinase), and laccase from Myceliophthora thermophila. The present invention further relates to laundry detergent and/or fabric care compns. comprising such modified enzyme(s). These

compns. provide a higher effective concn. of the enzyme at its substrate location and therefore, improved enzymic benefits.

AB An **endoglucanase** gene, which was shown to be identical to the previously sequenced engB gene [Attwood et al. (1993) Abstr. Ann. Meet. Am. Soc. Microbiol.], was isolated from a Clostridium **cellulovorans** genomic library. Because of the lack of transcriptional information concerning engB we examined its expression in C. **cellulovorans** and in the heterologous hosts Eschenchia coli and C. acetobutylicum following transformation of engB. Northern analysis suggested that both E. coli and C. acetobutylicum produced several transcripts of various sizes. C. **cellulovorans** produced a single transcript of 1600 bp with the relative amount of engB mRNA from cellulose-grown cells being much greater than that from cellobiose-grown cells. Primer extensions showed that engB was transcribed from a single transcription initiation site in C. **cellulovorans** preceded by sequences similar to promoter sequences found in Gram-positive bacteria. Primer extensions from both E. coli and C. acetobutylicum strains containing the engB gene showed multiple transcription initiation sites, none of which corresponded to the site determined in C. **cellulovorans**. We conclude that transcriptional control of the engB gene is less stringent in heterologous backgrounds and postulate that expression of the engB gene in C. **cellulovorans** is increased in the presence of cellulose.

ABSTRACT IS AVAILABLE IN THE ALL AND IALL FORMATS

AB A plant polysaccharide hydrolase **cDNA**, designated celD, was isolated from a **cDNA** library of the rumen fungus Neocallimastix patriciarum. The enzyme encoded by celD had **endoglucanase**, cellobiohydrolase and xylanase activities. Deletion analysis revealed that celD **cDNA** can be truncated to code for three catalytically active domains. Each domain had the same substrate specificity as the enzyme produced by the untruncated celD and also possessed cellulose-binding capacity. Substrate competition studies showed that carboxymethylcellulose and xylan appear to compete with methylumbelliferyl cellobioside for the same active site within each domain. Expression of celD transcript in the rumen fungus was constitutive and was not affected by the presence of cellulose in the culture medium.

AB An **endoglucanase** gene, engB, from C. **cellulovorans**, previously cloned into pUC19, has been further characterized and its product investigated. The enzyme, EngB, encoded by the gene was secreted into the periplasmic space of Escherichia coli. The enzyme was active against CM-cellulose, xylan and lichenan but not Avicel (cryst. cellulose). The sequenced gene showed an open reading frame of 1323 bp and coded for a protein with a mol. mass of 48.6 kDa. The mRNA contained a typical gram-pos. ribosome-binding site sequence GGAGG and a sequence coding for a putative signal peptide. There is high amino acid and base sequence homol. between the N-terminal regions of EngB and another C. **cellulovorans endoglucanase**, EngD, but they differ significantly in their C-termini. Deletion analyses revealed that up to 32 amino acids of the N-terminus and 52 amino acids of the C-terminus were not required for catalytic activity. The conserved reiterated domains at the C-terminus of EngB were similar to those from **endoglucanases** from other cellulolytic bacteria. According to deletion analyses, this region is not needed for catalytic activity.

AB A C. **cellulovorans** lambda gt11 gene bank was screened for endo-1,4-.beta.-glucanase [EC 3.2.1.4, EGase, Carboxy Me **Cellulase** (CMCase)] genes using a chromogenic substrate. Three genes (engA, engB, and engC) were isolated. The engB expressed that most active CMCase. The

engA encoded a bifunctional enzyme that displayed endo-1,4-.beta.-glucanase and .beta.-glucosidase activities. The 3 recombinant glucanases, when expressed in Escherichia coli, were partially degraded into multiform active enzymes as evidenced by their SDS-PAGE-CMC zymograms. None of the **clones** could degrade cryst. cellulose, thus supporting the hypothesis that the integrity of the C. **cellulovorans cellulase** complex was essential for its true **cellulase** activity.

AB A 5.8 kbp DNA fragment from C. **cellulovorans** (ATCC 35296) contg. the endo-.beta.-1,4-glucanase (1,4-.beta.-D-glucan glucanohydrolase, carboxymethylcellulase, CMCase; EC 3.2.1.4) gene (engD) was cloned in Escherichia coli. The **clone** harboring a subcloned 3.8 kb fragment in plasmid, pEQ52V, produced an enzyme that showed both endo-.beta.-1,4-glucanase activity as well as cellobiosidase activity. Zymograms with the engD encoded enzyme with carboxymethyl-cellulose as the substrate indicated that the mol. mass of the active protein was 50,000.

Characterization of the cellulose-binding domain of the Clostridium cellulovorans cellulose-binding protein A.

Goldstein MA, Takagi M, Hashida S, Shoseyov O, Doi RH, Segel IH.

Department of Biochemistry and Biophysics, University of California Davis 95616.

Cellulose-binding protein A (CbpA), a component of the cellulase complex of Clostridium cellulovorans, contains a unique sequence which has been demonstrated to be a cellulose-binding domain (CBD). The DNA coding for this putative CBD was subcloned into pET-8c, an Escherichia coli expression vector. The protein produced under the direction of the recombinant plasmid, pET-CBD, had a high affinity for crystalline cellulose. Affinity-purified CBD protein was used in equilibrium binding experiments to characterize the interaction of the protein with various polysaccharides. It was found that the binding capacity of highly crystalline cellulose samples (e.g., cotton) was greater than that of samples of low crystallinity (e.g., fibrous cellulose). At saturating CBD concentration, about 6.4 mumol of protein was bound by 1 g of cotton. Under the same conditions, fibrous cellulose bound only 0.2 mumol of CBD per g. The measured dissociation constant was in the 1 microM range for all cellulose samples. The results suggest that the CBD binds specifically to crystalline cellulose. Chitin, which has a crystal structure similar to that of cellulose, also was bound by the CBD. The presence of high levels of cellobiose or carboxymethyl cellulose in the assay mixture had no effect on the binding of CBD protein to crystalline cellulose. This result suggests that the CBD recognition site is larger than a simple cellobiose unit or more complex than a repeating cellobiose moiety. This CBD is of particular interest because it is the first CBD from a completely sequenced nonenzymatic protein shown to be an independently functional domain.

Roles of the catalytic domain and two cellulose binding domains of Thermomonospora fusca E4 in cellulose hydrolysis.

Irwin D, Shin DH, Zhang S, Barr BK, Sakon J, Karplus PA, Wilson DB.

Department of Biochemistry, Molecular and Cell Biology, Cornell University, Ithaca, New York 14853, USA.

PubMed Services

Thermomonospora fusca E4 is an unusual 90.4-kDa endocellulase comprised of a catalytic domain (CD), an internal family IIIc cellulose binding domain (CBD), a fibronectinlike domain, and a family II CBD. Constructs containing the CD alone (E4-51), the CD plus the family IIIc CBD (E4-68), and the CD plus the fibronectinlike domain plus the family II CBD (E4-74) were made by using recombinant DNA techniques. The activities of each purified protein on bacterial microcrystalline cellulose (BMCC), filter paper, swollen cellulose, and carboxymethyl cellulose were measured. Only the whole enzyme, E4-90, could reach the target digestion of 4.5% on filter paper. Removal of the internal family IIIc CBD (E4-51 and E4-74) decreased activity markedly on every substrate. E4-74 did bind to BMCC but had almost no hydrolytic activity, while E4-68 retained 32% of the activity on BMCC even though it did not bind. A low-activity mutant of one of the catalytic bases, E4-68 (Asp55Cys), did bind to BMCC, although E4-51 (Asp55Cys) did not. The ratios of soluble to insoluble reducing sugar produced after filter paper hydrolysis by E4-90, E4-68, E4-74, and E4-51 were 6.9, 3.5, 1.3, and 0.6, respectively, indicating that the family IIIc CBD is important for E4 processivity.

Mutation analysis of the cellulose-binding domain of the Clostridium cellulovorans cellulose-binding protein A.

Goldstein MA, Doi RH.

Section of Molecular and Cellular Biology, University of California, Davis 95616.

Cellulose-binding protein A (CbpA) has been previously shown to mediate the interaction between crystalline cellulose substrates and the cellulase enzyme complex of Clostridium cellulovorans. CbpA contains a family III cellulose-binding domain (CBD) which, when expressed independently, binds specifically to crystalline cellulose. A series of N- and C-terminal deletions and a series of small internal deletions of the CBD were created to determine whether the entire region previously described as a CBD is required for the cellulose-binding function. The N- and C-terminal deletions reduced binding affinity by 10- to 100-fold. Small internal deletions of the CBD resulted in substantial reduction of CBD function. Some, but not all, point mutations throughout the sequence had significant disruptive effects on the binding ability of the CBD. Thus, mutations in any region of the CBD had effects on the binding of the fragment to cellulose. The results indicate that the entire 163-amino-acid region of the CBD is required for maximal binding to crystalline cellulose.
